Python Pandas Guide

Python Data Science | Built-in learning library

Work with tables

A DataFrame holds rows and named columns. Start by checking column names, data types and missing values. Select the columns you need before summarizing your data. Keep the original input so you can repeat your analysis.

Try this example

```
import pandas as pd

scores = pd.DataFrame({
    'student': ['Asha', 'Ravi', 'Mina'],
    'score': [82, 67, 91],
    'batch': ['A', 'A', 'B']
})
print(scores.head())
print(scores.dtypes)
print(scores.loc[scores['score'] >= 80, ['student', 'score']])
print(scores.groupby('batch')['score'].mean())
scores.to_csv('scores.csv', index=False)
```

Practice

Add a row with a missing score. Inspect missing values with isna().sum(). Decide whether to exclude or replace missing scores and explain the choice. Read your exported CSV with read_csv and compare the row count.
