React Hooks Cheat Sheet

Full Stack MERN | Built-in learning library

Choose a hook

useState stores values that affect rendering. useRef holds a mutable value without triggering a render. useContext reads shared context. useEffect synchronizes with an external system. useMemo caches a calculation; useCallback caches a function identity. Use memoization when it solves a measured performance problem.

Counter example

```
import { useState } from 'react';

export default function Counter() {
  const [count, setCount] = useState(0);
  return (
    <button onClick={() => setCount(n => n + 1)}>
      Count: {count}
    </button>
  );
}
```

Practice

Add a Reset button. Then add a second counter and check that its state is independent. For subscriptions or timers, return a cleanup function from the effect. Keep ordinary Hooks at the top level of a component or custom Hook.
