TypeScript Handbook

TypeScript | Built-in learning library

Starter reference

Use string, number and boolean for primitive types. An array can be written as string[]. Object types describe required and optional properties. A union allows alternatives; narrow it before using operations specific to one member. Type annotations do not validate network data at runtime.

Typed functions

```
type Student = {
  name: string;
  score?: number;
};

function result(student: Student): string {
  if (student.score === undefined) return 'Not graded';
  return student.name + ': ' + student.score;
}

function formatId(id: string | number): string {
  return typeof id === 'string' ? id.trim() : String(id);
}

console.log(result({ name: 'Asha', score: 82 }));
```

Practice

Make score required and observe which calls need updating. Add a status union with three allowed values. Prefer precise types to any. This is an introductory study sheet; the linked handbook covers the language in greater depth.
